Abstract

The effect of tax on economic activities is an important issue in public finance. The fact that the existing system may decrease the investment motivation and consequently decrease the future life style is a great crisis. In addition to, the effects of tax system on capital formation, it can affect financial development and economic growth. In this paper, by simultaneous equations system in GMM method, the impact of capital gain tax on the capital formation and financial development in selected Europe Union countries (Austria, Belgium, Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Ireland, Italy, Netherlands, Spain and Sweden), will be studied in panel form. The results indicate that the capital gain tax growth rate, with one lag, increases the physical capital formation growth rate. Also, capital gain tax growth rate, with one lag, decreases the financial development growth and increases the economic growth rate.

Keywords: Capital gain tax, Capital formation, Economic growth, Simultaneous equations system, GMM.

JEL Classification: O16 - H24 - E22.

Introduction

Economic growth is one of the goals which are followed in every economy and it is of great importance for programmers and politicians because of the benefits and interests gained in the growth process. Achieving a high permanent growth in economy demands answering the following question: “what factors are involved in the rate of economic growth?” or “What factors and politics affect the economic growth rate and how”. The author's first supposed that financial development and capital formation are the main factors involved in economic growth. On the other hand, taxes and especially capital gain tax, affects the three-above-mentioned variables. So it is necessary to consider its positive and negative effects on economic growth and consequently on economic development. In recent years, the severe reaction of Iran’s economy to politics and changes of the financial markets indicates the prominent role of financial markets in Iran’s economy. If the financial markets perform its main tasks in decreasing the cost of information, facilitating the transactions, careful considering costs, providing fund for innovative activities, establishing a suitable source for providing capital for investment, economic growth will be facilitated [1]. One of the most important issues in economic growth literature, which is discussed a lot, is the impact of financial development on economic growth. There is more efficient financial sectors in developed countries because of having widespread financial institutes and organizations and because of using different financial tools and having suitable financial laws. However, the condition in developing countries is different from developed countries. Because of controlling a large part of financial system by government, having inefficient bank services,
shortage of resources, existing dual financial sector structure (formal and informal) and dominating the informal sector's operation, institutions and organizations don't have an efficient operation. So, some economists ascribe the dullness of economic growth in developing countries to inefficient and undeveloped financial sector. They recommend an organized reformation of this sector in order to achieve a more economic growth. Most economists emphasized on the establishment of physical capital, and human capital as the main factors involved in economic growth and development. High capital formation requires the development of financial intermediaries or briefly financial development. The idea, which introduces capital formation as a determinant factor in economic growth and is approved by experimental and theoretical studies, has existed in economy from the Adam Smith period. In this theory, it is supposed that the mechanism of achieving high amount of capital formation innately exists in economy and high economic growth is achieved by reinforcing this mechanism [2]. Also it is true that since economic growth leads to the development of skill level and workforce specialty and capacities, improvement of production quality and the rise of efficiency of using material capital and optimal implementation of them, causes the rise of investment in physical and human capital formation. Economic growth has an undeniable effect on the improvement of people's welfare level and more physical and human investment, employing new production technologies, presenting new knowledge in this field, are the main bases for growth process. Because of this effect on the output of physical and human investment, taxes can affect economic decision making and consequently growth rate. One type of taxes is capital gain tax which, depending on the growth selected model, has different effects on the economic growth. Saving and investment are two main canals, through which, capital gain tax can affect economic growth. Capital gain tax can affect investment in two ways: one through increasing capital cost. When capital gain tax rate increases, investment output rate decreases and capital cost increases. When the investment output is low, investment and capital stock decreases. When capital tension is lower than capital cost, the above-mentioned analysis is not acceptable. The second way, through which, capital gain tax affects investment is assets blocking. The results of asset blocking slow down the investment in new risky assets because investors are induced to postpone selling the taxable assets. This argument is true if the output rate related to new risky investment is not big enough to compensate the cost of paid tax of selling the assets. About the capital gain tax, capital gain tax rate change leads to investment output change after changing tax rate. The decrease in tax rate leads to increasing output rate after exerting the tax. The change in the output rate has two compensating influences on saving. The increase in the output rate can lead to increasing saving in the families (replacement effect). At the same time, the output rate increase makes it possible for families to keep low level of fortune (income effect). So, the effect of capital gain tax on personal saving depends on the resultant of the two-mentioned effects. Since financial development, capital formation and capital tax influence economic growth and since economic growth has some influence on the saving and investment variable and changes the above-mentioned factors, this study aims at investigating the effect of capital gain tax on capital saving, financial development and economic growth. After investigating the accomplished research, in the next part, the research patterns are presented and appraised and finally the results will be analyzed.

Background

Argger, brown & Rossi [3], in an article titled "transfer tax, capital gain tax, and house price" investigate the effect of capital gain tax and transfer tax on house price growth in 92 Switzerland regions in 1985-2009. The results indicate that house price growth in regions, where capital gain tax increased, is stable while in regions where capital gain tax decreased, is not the same. Also, in this study, the estimations are based on five periods: two deflations periods as 3 prosperity periods. The results shows that in deflation period, capital gain tax has no effect on house price growth, while in prosperity period, it is has a significant positive effect on house price growth. The results also indicate that the regions are divided into three regions, based on the tourism intensity: 1. High tourism intensity 2. Low tourism intensity 3. Mediocre tourism intensity. The results show that a 1% increase in capital gain tax rate leads to a 12% increase in house
price growth and a 1% increase in capital gain tax rate leads to a 43% increase in house price growth. However, in low and mediocre regions, changes in tax rate don’t have a significant effect on house price. Kilimani[4], in an article titled “the relationship between financial development and economic growth in Uganda: causality test” using time series data in the years 1970-2006 for Uganda, and regarding that economic growth is measured by real GDP and financial development is measured by M2 ratio to GDP, in order to investigate whether financial development leads to economic growth or economic growth leads to financial development, applying causality test concludes that financial growth leads to economic growth and consequently, economic growth leads to financial sector growth. Ahmad, horner & Rafiq [5], in an article titled “financial development and economic growth: experiences of selected economic development” investigate the relationship between financial development and economic growth in some selected developing countries (Brazil, Mexico, and Thailand). In this study, using panel data, estimated a Cobb-Douglas for the 3-mentioned countries. In most models, they concluded that financial development has a positive effect on economic growth. Ang & Mckibbin [6], in an article titled “financial liberation, financial development and growth: witnesses from Malaysia” using time series in the years 1960-2001 of Malaysia and using co-integration test and Granger analyst, concluded that both repressive politics and real interest rate have negative effect on financial development. Also, they found out that, although financial depth and economic growth related to each other positively, unlike the conventional findings, in long period of time, production growth leads to higher financial depth. Scully [7], in an article titled “taxes and economic growth” investigates the relationship between tax and economic growth in the United States in the years 1929-2004. Studies show that high tax rate and subsidy damage the efficiency of economy and cause to decrease the productive motivation in people and consequently decrease the economic growth. Economic growth results from productivity increase and the more the size of the government increases, the more the productivity decreases. So, there is an optimum size for government, determined by a tax level, which maximizes the growth. Using the data from the U.S in the years 1929-2004, estimates that the economic rate is about 23% of the GDP Young Lee & Roger Gordon [8] in an article titled “tax structure and economic growth” using panel data of 70 countries in the years 1970-1997 investigates the effect of tax on the economic growth and the results show that the effect of tax rate change the companies is negative. Fuest, Hurber & Nielsen [9], in an article titled “capital gain tax and house price fluctuations” investigate whether using OLG model, capital gain tax decreases the house price fluctuations or increases them. In this study, to investigate the effect of capital gain tax on house price fluctuations, the authors use the two periodic overlapping generation model. They show that those, who have bought their estate in a prosperity period, likely lose some of their properties when they want to sell in and those, who have bought their estate in depressive period, will have a great benefit and make a lot of money from selling them. Capital gain tax decreases the expected loss in these purchases in prosperity period, and also decreases the benefits of these purchases in deflation period. Fase & Abma [10], in an article titled “financial development and economic growth in selected Asian countries” using statistic data from nine developing southeast Asian countries in the years 1974-1999 tested the empirical relationship between financial development and economic growth. Using the causality test, they concluded that causality relationship is from financial development to economic growth. Seida & Wempe [11], in an article titled “Do the increases in capital gain tax rate affect the individual investors and commercial decisions?” investigate the effects of capital gain tax rate on the investors’ commercial decisions. To do this, they compared the exchange of profitable assets and detrimental assets before and after the tax reform. The results show that people tendency to sell their long-term profitable assets decreases while people tendency to sell their non-profitable assets increases. Steven & Benjamin [12], in an article titled “the decrease in capital gain tax, investment and growth” investigate the effect of capital gain tax rate in the U.S economy in 1995. They also explain how the decrease in capital gain tax rate affects the capital cost and consequently investment and growth. They concluded that the decrease in the capital gain income, considering capital gain as an inflation index, decreases business capital cost. They argue that the decrease in capital
cost increases and improves the U.S economy condition. They also argue that the increase in the capital stock leads to an increase in GDP. Also they argue that the nominal growth of economy doesn’t need to political change for production increase resulted from the decrease in capital gain tax. Goldsmith [13], in an article titled “development and financial structure”, using the data from 35 countries in the years 1960-1963, investigates the relationship between financial intermediaries and growth and concludes that the results show that financial development index has a positive effect on real per capita as an economic growth index. In each of the above-mentioned studies parts of the factors involved in economic growth for example the effect of financial development or the effect of capital formation on growth is investigated, but there are no studies to investigate capital formation, financial development, and economic growth. Because of the effect of capital gain tax on saving, investment, and economic growth, the importance of this study is the investigation of the effect of capital gain tax on capital formation, financial development, and economic growth in the years 1970-2014.

**Model Specification**

The base of economy is economic growth. One of the main purposes of economic growth studies understands the cause of enormous changes in the world per capital income. Most research models used for this purpose are endogenous models. Endogenous growth theory is a simple concept for economic growth which comes true inside the system or inside the country. In general, there are two main reasons for developing endogenous growth models. Firstly, the growth of economy and production in industrial countries is higher than their growth in the last century. Such high growth requires theories and reasons which are able to explain fully these economic and technological growths. Secondly, endogenous growth theory represents another branch of development which is not dependent on business. The first model of endogenous growth tried to show that technological improvement result from the individual activities. In 1980s, Roomer & Lucas applied the endogenous technology in the growth models. They considered the technology as a peripheral effect of investment of private sector. So, the technology is pure public good and consequently, the businesses are the receivers of the price. A large group of endogenous growth patterns are introduced as patterns. In the endogenous growth models, with the presupposition of existing of just one cargo and one type of institutes, that is, capital, the production function is determined as the following [14,15]:

\[
\frac{dY_t}{dt} = \frac{\partial f}{\partial K_t} \frac{dK_t}{dt}, \quad \frac{dT/dt}{Y_t} = \left(\frac{\partial f}{\partial K_t}\right) \left(\frac{dK_t/dt}{Y_t}\right),
\]

The left statement is equal to production growth rate and the right statement is equal to the ratio of growth rate to production. Here the growth rate is equal to the production of final capital. Also the rate of investment is equal to:

\[
\frac{dK_t/dt}{Y_t} \quad I_t = \frac{1}{Y_t},
\]

In which the capital amount change is equal to investment. Here the presupposition is that the economy is closed and in balanced mode, financial market equalize saving and investment. Also it is supposed that a part of saving is not used in investment. Only a part of saving is used in investment:

\[
I_t = \varphi S_t = \varphi s Y_t
\]

In which “s” represent saving rate and is equal to:

\[
g_y = \left(\frac{\partial f}{\partial K_t}\right) \left(\frac{dK_t/dt}{Y_t}\right) \quad \frac{dK_t}{dK_t} \quad \frac{1}{Y_t} \quad \frac{\partial f}{\partial K_t} \varphi
\]
Now, combining the equation, we will have the following formula:

\[ g_y = f(K_t) \phi_s. \]

We can deduce that financial media can affect the economic growth. So, we can define models, such as King & Levin, in which financial development is one of the most effective variables in economic growth so, we can write:

\[ Y_t = f(FD_t, Z_t) \]

The mathematical model of the above-mentioned relationship is as following:

\[ Y_t = \alpha_0 + \alpha_1 Z_t + \alpha_2 FD_t + \alpha_3 K_t + \mu_t \quad (1) \]

Also, Economic growth leads to financial development and due to the increase of saving and investment level, it affect capital formation. So we can write:

\[ FD_t = \beta_0 + \beta_1 Z_t + \beta_2 Y_t + \mu_t \quad (2) \]

Also, capital gain tax, due to its effect on capital formation, affects economic growth and we can write:

\[ K_t = \gamma_0 + \gamma_1 Z_t + \gamma_2 FD_t + \gamma_3 Y_t + \gamma_4 CGT + \mu_t \quad (3) \]

So that: \( Y_t \) Is economic growth \( Z_t \) is a vector of the other independent variables:

Trade Opness (TOP) which is the ratio of the total annual import and export to GDP FOP is Financial Opness. To measure this variable, chin-Ito index is used. Because the Inflation has an inevitable effect on the other economic variables, especially growth rate, consumer price index growth affects the economic growth. Also, because in most countries, a considerable part of the effective factors in GDP and economic growth is determined by the public sector, Government consumption Expenditure index in the GDP can be a useful variable (GOV/GDP). Economic Growth Rate Fluctuation is another variable. Also In this study, the number of graduates is considered as human capital index. \( K_t \): In this formula, is physical capital formation? In this study, FD, financial development index is the ration of money to liquidity \( \frac{M_1}{M_2} \). \( \mu_t \) Is residual Also, capital gain tax is another factor which affects economic growth. Since there is no information about this variable in Iran, here by CGT, we mean the wealth tax. It is necessary to mention that, in this study, all the variables are considered in the rate form. Empirical work, in this study, are based on simultaneous equations system. So, the effect of capital gain tax on the capital formation, financial development and economic growth in Austria, Belgium, Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Ireland, Italy, Netherlands, Spain and Sweden is investigated in the years 1970-2014.

**Research Hypotheses**

- There is no relationship between economic growth rate and financial development growth rate.
- There is no relationship between economic growth rate and capital formation growth rate.
- There is no relationship between financial development growth rate and capital formation growth rate.
- There is no relationship between capital gain tax growth rate and capital formation growth rate.
- There is no relationship between capital gain tax growth rate and financial development growth rate.
- There is no relationship between capital gain tax growth rate and economic growth rate.

**Methods, Experience Tools, Data Analysis**

It is necessary to determine the condition of equation recognition before the analysis of related patterns which are in the form of simultaneous equations system. Also, in this study, GMM is used to estimate the equation. This method has some advantages such as considering individual differences and more information and eliminating of existing biased in cross sectional regression. Using this method leads to more exact and efficient estimation and the less co-linearity in the
GMM (generalized method of moments). Since the dependent variable with a lag in the right is related to residual. This problem leads to OLC estimator become inconsistency and biased. Also, the GLS estimator’s random effects become biased in a dynamic mixed panel data. So, to estimate the applied simultaneous equations system in the study, the E views econometric software and GMM are used. Also the standard test for validation of moving limitations in GMM estimation process, is Sargan test of over identify concentrates. J-statistic test in GMM estimation, under the null hypothesis of Moving limitations is valid. In other word, in this test, null hypothesis show the appropriate selection of tool variables used in the pattern and also it is an approval for tool variables. The sargan statistic is asymptotically distributed chi-square with degrees of freedom equal to the number of over-identifying restrictions. The number of over-identifying restrictions is equivalent to the number of extra instruments (instrument-parameters).

**Empirical results**

In this study using the related simultaneous equations system and estimating it in GMM method, the effect of capital gain tax on capital formation, financial development and economic growth is investigated in selected countries in the years 1970-2014 and the results will be analyzed.

**Recognition of Equation**

Before estimating the equations, it is necessary to determine the condition of equation. So, Rank and Order condition is used for equation recognition. In the table (1-6), order condition based on recognition ability. Is used in which ‘k’ represents exogenous variables and ‘m’ represents endogenous variables in the models. Also, ‘k’ and ‘m’ are representatives of endogenous, exogenous variables in under-investigation equations. Regarding the results of (1-6), in all three equations, \( K - k > m - 1 \) is true which is based on the order condition of given equations, are over identified Based on the ranking condition, in a model including M equations and M endogenous variable, an equation will be determined if and only if we can write at least one nonzero degree determinant of coefficients of other equations [16].

Since for all the three under investigation equations, we can write a nonzero determinant, so the Equations are identified and we can use (3SLS)

**Stationary Test**

Macro-economic variables often include a random method (Unit Root) which is eliminated by one differencing. Since the existence of such process invalidate the estimation and statistical inference in conventional econometrics method, so the first step in econometrics analysis in modern methodology is determining degree of integration (number of Unit Roots). Non-standard variables turning into stationary variable after differencing are called integrated of 1degree or I (1). Other
variables may be stationary or stationary in trend (that is mean I(0)). In addition, it is possible that some variable turn into stationary variables after several differencing (for example d times). So they are called integrated of d degree or I(d) [17].

In this study, augmented Dickey Fuller test is used to investigate the properties of stationary data. The results of this test obtained from E views software are presented in table (3-6). As shown in the table, all the variables used in the pattern are stationary and applying them in the model doesn’t damage the results.

Regarding the results, Durbin-Watson statistics value for all the three equations is between 1.5 to 2.5 and shows that there is no correlation between residuals. It is necessary to mention that the statistic J is equal to 23.78 and chi statistics value is twice as much as 0.07 which shows that the entered tool variables in the system of simultaneous equations are valid and all the patterns are estimated correctly. Using the results, the analysis of results will be investigated based on the research hypotheses and the related tests. The results of the present study about the first hypothesis “economic growth rate and financial development growth rate don't affect each other” show that financial development growth rate has not effect economic growth rate but economic growth rate with two lags decreases financial development growth rate about 0.49 unit. There are different ideas about the relationship between economic growth and financial development. The first idea is that financial development leads to economic growth. This idea is known as “supply idea”. The second idea is that economic growth leads to the demand for financial services and the need for new financial tools. So, economic growth results in the formation of financial development. The third idea is that there is no significant relationship between economic growth and financial development. The fourth idea is that the relationship between economic growth and financial development is bilateral and concurrent or in other word, both supply and demand theories are underway [18]. In this study is confirmed Demand theory. Also, economic growth rate decreases financial development growth rate. It can be argued that decreasing in liquidity in banking and credit system can be due to financial crisis in the years 2007-2012. By spreading this crisis in the large financial institutes, it turned into a systemic crisis in financial markets and consequently leads to a decrease in stock price and the fall of stock. Bankruptcy of some banks and financial institutions, which is the natural consequences of this process, leads to an anxiety in financial markets, sharp decline in credit, economic deflation, and unemployment increase. The main causes of the crisis can be the housing market boom in the United States, financial innovation in high-risk mortgage loans, lack of adequate oversight on stock exchange, on big financial institutes, and on speculators in world financial markets.1 The results of the present study on the second hypothesis _economic growth rate and capital formation growth rate don’t affect each other_ show that capital formation growth rate increases economic growth rate about 0.42 unit and economic growth rate increases capital formation growth rate about 2.4 units. The rate increases importance of investment in social economic development growth process is emphasized in most economic growth theories. Regarding the shortage of resources of investment and the necessity of efficient allocating of these resources to evoke economic growth, it is necessary to recognize the relative advantage of a countries in the field of allocating resources and by directing investment of resources to the most productive and efficient sectors, a field for efficient use of limited resources to accelerate economic growth can be provided [19]. So, we can say that investigation in the physical resources such as equipment and machinery,
increases the individual power and consequently economic growth and vice versa. Also the results of the third hypothesis _financial development growth rate and capital formation growth rate don’t affect each other” show that financial development growth rate with 1 lag, does not affect physical capital formation growth rate but physical capital formation growth rate decreases financial development growth about 0.29 unit. Unsuitable financial structure yearly (loss formation, bank debts), not using new accounting method for assessment and surveillance financial condition, not existing a continuous relationship between businesses and the capital markets (the limited sector which exist), shortage of liquidity and disorder in the cash flow, results in this decrease. Based on the results of the above table, about the last three hypothesis “capital gain tax growth rate doesn’t have no effect on the changes of capital formation growth rate, on financial development growth rate, on economic growth rate” we can say that: the increase of capital gain tax growth rate with 1 lag, increases capital formation growth rate about 0.03 unit. Also, capital gain tax growth rate with 1 lag decreases financial development growth rate about 0.009 units and increases economic growth rate about 0.013. Also, regarding the above-mentioned information and the results of the forth hypothesis _capital gain tax rate have a positive effect on the physical capital formation_ and also the results of the third and second hypotheses _physical capital formation have a negative effect on the financial development growth rate and physical capital formation has a positive effect on the economic growth rate and also regarding the information about the Model Specification and presented theoretical concepts, since capital gain tax rate, using physical capital formation growth rate, affect economic growth and financial development variables, we can say that capital gain tax growth rate has a negative effect on financial development growth rate and has a positive effect on economic growth rate.

Results and Suggestions

Taxes can affect economic decision and consequently affect growth rate because of their effect on the physical and human investment output. One type of taxes is capital gain tax. Capital formation, financial development, and economic growth are variables affected by tax structure. This study aims at investigating the effects of capital tax on the relationship between capital formation, financial development and economic growth. So, in this study, the effect of capital gain tax on capital formation, financial development and economic growth in the years 1970-2014, using simultaneous equations system and GMM method has been investigated in panel format in Denmark, Stevia, Italy, Netherlands, Swede, and Iran. The results show that financial development growth rate does not affect economic growth rate but economic growth rate with 2 lags decreases the financial development growth rate about 0.49 units. Capital formation growth rate increases economic growth rate about 0.42 units and economic growth rate increases capital formation growth rate about 2.4 units. Financial development growth rate with 1 lag, does not affect physical capital formation growth rate but physical capital formation growth rate decreases financial development growth rate about 0.29. Also, the findings show that the increase of capital gain tax growth rate with 1 lag, increases capital formation growth rate about 0.03 unit. Also capital gain tax growth with 1 lag, decreases financial development growth about 0.009 unit and increases economic growth rate about 0.013.Also, the amount of $J$ statistic is equal to 23.78 and the amount of chi statistics is equal to 0.07 which show that the entered tool variables are valid in the system of simultaneous equations and all the patterns are estimated correctly. Regarding the results of estimating patterns, we can conclude that if financial development can provide suitable condition for optimal allocation of resources and also the increase of capital efficiency, so it can increase production and economic growth and vice versa. Also, regarding the results since the negative effect of capital formation growth rate on financial development growth rate and can be due to unsuitable financial structure (yearly loss formation, bank debts ...) and not using new accounting method for assessing and financial condition, not existing a continuous and valid relationship between involved businesses and capital markets (the limited existing sector), lack of liquidity and disorder in cash flow and .... It can be mentioned that the government interference to create assurance for clearance and liquidation by planning a practical process accepted by obliges and debtors and establishment of a situation for production
unit which is able to access suitable liquidity flow through continuously improving activity levels. Accepting loan applicants and lending loan to productive units especially troubled ones by banks without considering the normal studies, if the loan applicant can give guaranty, are factors that can lead to positive effect of financial development growth rate and capital formation growth rate on each other. Also negative effect economic growth rate on financial development growth rate can be considered due to the financial crisis in the years 2007-2012. So, we can say that deal with financial crises requires international cooperation, especially is coordinated monetary policy in major industrial countries by central banks. The IMF is seeking the new rules controlling the operation of international financial institutions could reduce or controls the effects of such crises. Also, since capital gain tax affect some economic variables such as economic growth, investment, saving, capital formation, companies' financial policy, families portfolio, capital cost, demand for assets, the number of assets exchange, it is necessary that politicians, considering the existing laws and policies, notice the effects of capital gain tax on these variables [21-33].
